**ABSTRACT:** At the College Farm, Navsari Agricultural University, Navsari (Gujarat), a field experiment was carried out in the summer and *kharif* of 2021 and 2022. The study included four main plot treatments, namely, T<sub>1</sub>: Green gram, T<sub>2</sub>: Cowpea, T<sub>3</sub>: Dhaincha and T<sub>4</sub>: Fallow which were sown in summer season, replicated thrice in a randomized block design. Summer legume residues, namely green gram (T<sub>1</sub>) and cowpea (T<sub>2</sub>), were incorporated after final crop harvest, while dhaincha (T<sub>3</sub>) was incorporated at 50% flowering in corresponding plots. Each main plot treatment was carried out throughout the *kharif* season was divided into six sub-plot treatments as levels of recommended dose of fertilizer to *kharif* rice, which include W<sub>1</sub>: 100% RDF, W<sub>2</sub>: 75% RDF, W<sub>3</sub>: 50% RDF, W<sub>4</sub>: 75% RDF + 25% N from FYM, W<sub>5</sub>: 50% RDF + 50% N from FYM, and W<sub>6</sub>: No-fertilizer application; resulting in twenty-four treatment combinations replicated thrice in a split plot design. Results posed that the higher (₹/ha 95332, 108322, 101744), net returns (₹/ha 33478, 46044, 39678) was also recorded higher in rice grown in dhaincha incorporated plots with BCR of 1.54, 1.74, 1.64 in 2021, 2022 and in pooled study respectively. With the application of 100% RDF, maximum gross and net returns (/ha 111152, 51341; 125096, 64761; 118050, 57977) and BCR (1.86, 2.07, 1.97) were greater, while the lowest BCR (1.05, 1.21, 1.13) was in 2021, 2022, and on a pooled basis. Higher gross and net returns were observed in the green gram-rice cropping sequence during the pooled study, with a BCR of 2.22 in the treatment green gram-100% RDF (T<sub>1</sub>W<sub>1</sub>) and the lowest being in treatment T<sub>4</sub>W<sub>6</sub> (1.03). Based on the findings of the two-year experiment, it was observed that introducing dhaincha with 100% RDF (Recommended Dose of Fertilizer) yielded positive financial outcomes. Additionally, considering the cropping sequence, it was determined that green gram during the summer season followed by rice cultivation with 100% RDF resulted in greater financial advantages.

### INTRODUCTION

The Rig Veda and Mahabharata both make references to rice (Prasad *et al.*, 2016), which highlights its significance as a staple food for nearly half of the world's population. This crop holds great importance, accounting for approximately 40% of the nation's total production of food grains. Since rice consumption constitutes 90% of the global food intake, it becomes crucial to ensure global food security. To maintain the current per capita availability of rice (69 kg/year) and keep land productivity constant, the demand for rice is projected to increase by 70% in the next 30 years. This information underscores the importance of addressing the growing demand for rice while sustaining agricultural productivity (Patra and Haque 2011). Legume crop wastes are a valuable source of plant

nutrients and essential for the stability of agricultural ecosystems. The yearly in situ burning of over 23 Mt of rice residues in northwest states resulted in a loss of 9.2 Mt C equivalent to CO<sub>2</sub> load (NAAS, 2017). Rice productivity and rice-based systems' sustainability are at risk due to (1) dwindling resources (land, water, labour, and machinery), (2) inefficient input use (fertiliser, water, herbicides, insecticides, etc.), and (3) rising cultivation costs (Bhagirath *et al.*, 2017). The degradation of soil health is accelerating due to improper management practices, excessive use of fertilizers, and various other factors. Adopting the approach of residue integration can effectively reduce the burning of agricultural waste and mitigate the negative impact of modernization, all while enhancing soil fertility. To restore the soil's productivity and

promote sustainable agriculture, it is crucial to incorporate legumes into the crop rotation, ensuring proper soil coverage. In order to address the rising demand for fertilizers and improve crop yield, it is essential to consider an alternative approach that involves reducing fertilizer usage while increasing productivity. One potential solution is to optimize the use of crop wastes, which could potentially lead to higher rice output and lower cultivation expenses. To better understand the economic implications, further research is required to assess the feasibility of integrating crop residue and different levels of nutrient dosages in *kharif* rice cultivation.

## METHODOLOGY

In the summer and *kharif* seasons of the years 2021 and 2022, a field experiment was carried out at the College Farm, Navsari Agricultural University, Navsari (Gujarat). The experimental field's soil had a clayey texture, a medium level of organic carbon, low levels of readily available nitrogen and  $P_2O_5$ , and a high level of readily available  $K_2O$ . The soil was slightly alkaline in reaction. The experiment conducted included four main plot treatments, namely, T<sub>1</sub>: Green gram, T<sub>2</sub>: Cowpea, T<sub>3</sub>: Dhaincha and T<sub>4</sub>: Fallow which were sown in summer season, replicated thrice in a randomized block design. Summer legume residues, namely green gram (T<sub>1</sub>) and cowpea (T<sub>2</sub>), were incorporated after final crop harvest, while dhaincha (T<sub>3</sub>) was incorporated at 50% flowering in corresponding plots. Each main plot treatment during the *kharif* season was divided into six sub-plot treatments as levels of the prescribed fertiliser dose for *kharif* rice, which include W<sub>1</sub>: 100% RDF, W<sub>2</sub>: 75% RDF, W<sub>3</sub>: 50% RDF, W<sub>4</sub>: 75% RDF + 25% N from FYM, W<sub>5</sub>: 50% RDF + 50% N from FYM, and W<sub>6</sub>: No-fertilizer application; resulting in twenty-four treatment combinations replicated thrice in a split plot design. The economics of summer legumes (green gram, cowpea, dhaincha) and rice was worked out by considering the prevailing market rates for different inputs and produces. The cost involved and the returns obtained under different treatments is very important aspect for determining the overall advantages. It was worked out in terms of net returns and benefit cost ratio (B:C ratio) to ascertain the economic viability of the treatments. The treatment wise cost of cultivation (₹/ha) was calculated by considering the item wise prices/rates for respective years. Selling price of each kilogram of summer legumes and rice was taken from minimum support price. The gross realization (₹/ha) was worked out based on pod and stover yields of summer legumes (green gram, cowpea, dhaincha) and rice for each treatment considering prevailing market prices. The net realization (₹/ha) for individual treatment was worked out by deducting the total cost of cultivation of each treatment from gross realization of respective treatment. Net returns (₹/ha) = Gross returns (₹/ha) – Cost of cultivation (₹/ha)

Benefit-cost ratio which gives an indication of the monetary gain over every rupee invested under a particular treatment. The ratio of each treatment was

calculated by dividing the net realization by the cost of cultivation of respective treatment.

B : C ratio = Gross return (₹/ha)/Cost of cultivation (₹/ha)

Rice equivalent yield (kg/ha)

The conversion of summer legume yield and rice grain yield into rice equivalent yield (kg/ha) was determined based on the prevailing market prices for both crops. The following equation was used to determine the rice yield for the two different treatments.

$$REY (kg/ha) = \frac{Ya \times Pa}{Pb} + \frac{Yb \times Pb}{Pb}$$

Ya - Yield of summer legumes (kg/ha)

Yb - Yield of rice (kg/ha)

Pa - Price of summer legumes (₹/kg)

Pb - Price of rice (₹/kg)

## RESULTS AND DISCUSSION

The gross return, net return, and BCR were remarkably influenced by preceding summer legumes and their residue incorporation and nutrient doses in *kharif* rice (Table 1-3). The highest net returns were obtained with dhaincha (T<sub>3</sub>, Rs. 33478, 46044 and 39678 in 2021, 2022 and pooled respectively). The BCR was 1.54, 1.74 and 1.64 during 2021, 2022 and pooled respectively. Even though extra cost was included for residue incorporated plots, the higher grain yield might have compensated the net returns. The lower returns were recorded in fallow plots (T<sub>4</sub>) with BCR of 1.25, 1.41 and 1.33 in 2021, 2022, and pooled respectively. The reason behind this could be attributed to the fact that rice grown in dhaincha-integrated plots yielded higher quantities of both grain and straw compared to rice cultivated in green gram, cowpea, and fallow treatments, as documented by Anitha and Mathew (2011). Among the various factors influencing the increased grain output, enhanced nutrient availability and reduced cultivation expenses played a significant role, as stated by Premalatha (2017).

The nutrient doses favourably influenced the net returns in both the years. Application of 100% RDF (W<sub>1</sub>) recorded maximum gross and net returns (₹/ha 111152, 51341; 125096, 64761; and 118050, 57977) in 2021, 2022 and pooled study respectively. The BCR noticed was 1.86, 2.07 and 1.97 respectively in 2021, 2022 and pooled study in 100% RDF (W<sub>1</sub>). The lower returns were recorded in No-fertilizer treatment (W<sub>6</sub>) with BCR of 1.05, 1.21 and 1.13 in 2021, 2022 and pooled study respectively (Table 1,2,3). Similar results were found by Jat *et al.* (2011). In contrast to W<sub>4</sub>, W<sub>5</sub>, where cultivation expenses increased as a result of using FYM combined with fertiliser, W<sub>1</sub> treatment had reduced cultivation costs and improved grain and straw yields (Bora *et al.*, 2014). In comparison, the yields in W<sub>2</sub>, W<sub>3</sub>, and W<sub>6</sub> were low. Surprisingly, the summer fallow-No fertiliser treatment (T<sub>4</sub>W<sub>6</sub>) showed positive net returns in 2022 (Table 2) and in pooled study (Table 3), but it had negative net returns in 2021 (Table 1). This implies that not utilising fertiliser resulted in decreased yield and economic benefits for the farmer (Moolaram *et al.*, 2011; Saisravan *et al.*, 2016).

**Economics of Summer Legumes-Kharif Rice Sequence.** The gross return, net return, and BCR were remarkably influenced by preceding pulses, residue management and nitrogen levels (Table 4). The highest gross and net returns was obtained with green gram-rice sequence with application of 100% RDF (₹/ha 202077 and ₹/ha 111140 respectively) during pooled study. The BCR was 2.22.

The residue incorporated plots proved their significance in recording higher gross returns, net returns, and BCR. Though in rice economics (only *kharif*), dhaincha proved to be higher contributor for gaining more returns but in the case entire sequence green gram-rice (summer + *kharif*) proved to be better when compared to dhaincha-rice sequence with application of 100% RDF. This might be attributed to income earned through seed yield of green gram where there is no seed yield in dhaincha (Saisravan and Ramana 2014). Though the yield of rice recorded in dhaincha incorporated plots was higher, the economic returns for the entire sequence was higher in green gram-rice sequence and it was followed by cowpea – rice sequence. In these sequences the yield of green gram and cowpea were recorded along with the yield of rice whereas in dhaincha-rice sequence only yield of rice

was considered. Hence, in this cropping sequence green gram incorporated followed by *kharif* rice was better (Ramalakshmi *et al.*, 2015).

**Rice Equivalent Yield.** Significantly higher rice equivalent yield was recorded in green gram (T<sub>1</sub>, 6949, 7542, 7246 kg/ha) followed by cowpea (T<sub>2</sub>), dhaincha (T<sub>3</sub>) and fallow plots (T<sub>4</sub>, 2982, 3090, 3036 kg/ha) in descending order during 2021, 2022 and pooled study respectively. This could be attributed to the absence of seed yield in dhaincha, whereas seed yield in green gram and cowpea was recorded, resulting in an increase in rice equivalent yield.

Significantly higher rice equivalent yield (Table 5) was noticed in 100% RDF (W<sub>1</sub>) with a yield 5997, 6284, and 6141 kg/ha in 2021, 2022 and pooled respectively and lowest was recorded in 4035, 4320 and 4177 kg/ha in No-fertilizer application (W<sub>6</sub>). This is most likely attributable to higher grain yields in the 100% RDF (W<sub>1</sub>) treatment when compared to the other treatments and there was lesser grain yield in the No-fertilizer application treatment (W<sub>6</sub>) and better utilization of nutrients which were readily available through fertilizer when compared to FYM treatments (Barkha, 2020).

**Table 4: Economics of summer legumes – kharif rice cropping sequence as influenced by different treatment combinations (Pooled 2021 & 2022).**

Treatments	Total cost of cultivation (₹/ha) (Rice + summer legumes)	Grain yield of rice (kg/ha)	Straw yield of rice (kg/ha)	Seed yield of summer legumes (kg/ha)	Straw yield of summer legumes (kg/ha)	Returns from grain yield of rice (₹/ha)	Returns from straw yield of rice (₹/ha)	Returns from seed yield of summer legumes (₹/ha)	Returns from straw yield of summer legumes (₹/ha)	Total gross returns (₹/ha)	Total net returns (₹/ha)	Benefit cost ratio

## CONCLUSIONS

Dhaincha incorporation considerably increased gross return, net return, and BCR over other summer legumes and fallow. With 100% RDF, the gross return, net

return, and BCR all increased. Similarly, at 100% RDF, rice crops sown after dhaincha incorporation had a much higher net return and B:C ratio than crops sown following summer fallow with no fertilizer application.

Green gram had a higher rice equivalent with 100% RDF. When the summer legume-kharif rice sequence was assessed, the green gram-rice sequence had better economic returns and BCR.

#### FUTURE SCOPE

In legume-cereal rotations, the beneficial effects of legumes may not be immediate, 5-15 years long term experiments may be necessary to understand the nutrient levels of soil and yield which reflect in increasing returns and reducing cost of cultivation by decreasing cost of fertilizers as incorporation of legume residues provide nutrients.

**Acknowledgement.** I extend my sincere thanks to professor and head Dr. H.M. Virdia and to my committee members, my seniors for giving me proper guidance throughout the course study. The Gujarat state government granted financial support for the current investigation under “SHODH - Scheme for Developing High Quality Research, Education Department,” which is gratefully recognised.

**Conflict of Interest.** None.
